

It has been shown for the retina of nonprimate mammals (Franze et al., 2007; Agte et al., 2011; Labin et al., 2014), and proposed for the human and avian retina (Labin et al., 2014; Zueva et al., 2014), that Müller cells act as living optical fibers which guide the light with minimal intensity loss through the inner retinal layers toward the photoreceptors.

Cells act as guides, i.e., optical fibers, and/or light collectors, e.g. Müller cells.

Retinal neurons detect light.

Müller cells support the retinal tissue.

The last sentence on this page remains visible.
